Spells of Job Search and Layoff... and Their Outcomes

INTRODUCTION

This report presents an analysis of the spells of job search and layoff that began in 1984 and the outcomes of those spells. The data provide a rare glimpse of some of the characteristics of these spells—who experienced them, how long they lasted, whether health and unemployment insurance coverage was in force—and their outcomes—how many ended as a result of a job or by a withdrawal from the job market. As was reported by the Bureau of Labor Statistics (BLS), the Nation's economy during this period was still recovering from the 1981-82 recession and employment was growing vigorously and unemployment was dropping sharply.¹

The data on spells of job search and layoff discussed here are different from the official unemployment data reported by the BLS. The BLS data are cross-sectional, that is, they indicate how many people were unemployed at a *point-in-time*. Embodied in that estimate are the persons who have just entered and exited the unemployment pool as well as those who remained unemployed. The data on spells of job search and layoff discussed in this report are longitudinal. They relate to the experience of the same people *through time*, that is, from the time they began looking for work or periods of layoff to their completion of the spells of job search or layoff.

The distinction between these two types of data is an important one. With the official unemployment data, it is difficult to observe changes in the economic welfare of the same individuals that may take place during a period of job search or layoff. Similarly, it is difficult to observe the outcomes of spells, that is, whether individuals either found or returned to jobs or withdrew from the labor force. With longitudinal data, these and other matters associated with the spell of job search or layoff can be examined.

The source of the data on spells of job search and layoff examined in this report is the 1984 panel of the Survey of Income and Program Participation (SIPP), a longitudinal survey of approximately 2 1/2 years duration. Although the primary purpose of this survey is to collect information on the incomes received by individuals and the extent to which they participate in Federal

government transfer income programs, it also collects information on labor force activity. The linkage of the labor force data to the income and program participation data in a longitudinal context make them particularly useful for examining such subjects as the economic welfare of persons looking for work and on layoff from jobs.

The BLS's employment and unemployment statistics are the Federal government's official estimates and they are collected in the monthly Current Population Survey (CPS). This survey has provided policy makers and researchers with monthly labor force information since the 1940's. In addition, in the March CPS, supplemental questions are asked about the annual work experience of individuals in the previous calendar year. Labor force data from SIPP can enhance what we have learned from both the monthly and March CPS supplement, and it is in this context that this report should be viewed. Differences in labor force concepts and survey procedures exist between the SIPP and CPS, so data comparability is problematic. (See appendix B for a description of some of these differences.) Furthermore, since the SIPP sample is considerably smaller than the CPS, the data results are subject to greater sampling variability (see appendix C).

HIGHLIGHTS

(The figures in parentheses signify the 90 percent confidence intervals of the estimates.)

- In 1984, 26.7 (± 0.7) million spells of job search and layoff began and were completed either in that year, 1985, or early 1986. These spells were attributed to 21.7 (± 0.5) million persons. Women made up 11.7 (± 0.4) million of the total and men 10.0 (± 0.4) million.
- The "approximate" average length of a spell of job search or layoff was 3.4 (± 0.1) months. The average for men was 3.6 (± 0.2) months and for women, it was 3.2 (± 0.1) months.
- Of the 11.0 (± 0.4) million persons beginning their first spell of job search or layoff in 1984 and who had health insurance coverage previous to the spell, 20.1 (± 1.5) percent either had no coverage or only some coverage during the spell.
- About 54.0 (± 6.1) percent of the spells of job search and layoff of 5 months or longer experienced by men aged 25 to 54 were covered by unemployment insurance.

¹See Richard Devens, Jr., Carol Boyd Leon, and Debbie Sprinkle, "Employment and Unemployment in 1984: A Second Year of Strong Growth in Jobs," *Monthly Labor Review*, February, 1985, pp. 3-15.

- About two-thirds—67.4 (± 1.3) percent—of the total spells ended with a job. Men were more likely to end their spells with a job than women, and Whites more likely than Blacks and Hispanics.
- On average, the hourly earnings of jobseeking workers on their new job—\$5.81 ($\pm .16$)—were lower than on their previous job—\$6.18 ($\pm .17$).
- For those persons who had no previous job during the survey (possibly new entrants or re-entrants to the labor force), but after a period of search took a job, hourly earnings averaged \$4.46 ($\pm .19$).
- For persons who did not find jobs after their first spell of job search or layoff, average monthly household income fell from \$1,878 (± 82) before the spell began to \$1,737 (± 78) after the spell ended.

DEFINING SPELLS OF JOB SEARCH AND LAYOFF

Spells of job search and layoff are periods of time in which jobless persons are actively looking for work or have been released from jobs that they may or may not be called back to. Such spells are commonly associated with persons who lose their jobs (or are laid off) as a result of a business slowdown or plant closing. But other spells arise, for example, when persons quit their jobs to find better ones, or when persons start looking for work for the first time. Still others come about when individuals who have been out of the labor force for some time decide to go back to work.

Most spells of job search and layoff have identifiable beginnings and endings because they involve events to which persons attach some significance. But some spells are not as identifiable. Researchers have found that for certain groups in the population the distinction between looking for work and being outside the labor force is weak.² A jobseeker, after a period of unsuccessful job search, may become discouraged and give up looking for a while, but then resume the search later on. In such cases, whether or not the individual experienced one spell or a series of spells is difficult to determine.

It should be noted that a person can experience more than one spell of job search or layoff in the course of a year. For example, a young college graduate may "job hop" before finding the right job and experience two or three spells of job search, or a construction worker may be laid off several times in the year after construction projects are completed.

The labor force information collected in SIPP reflects, to some degree, the movement of persons into and out of spells of job search and layoff. This is because survey

respondents were interviewed every 4 months between the second half of 1983 and the first half of 1986, thereby providing a panoramic view of their labor force behavior. Respondents were asked to recall the weeks in which they had jobs, and if they did not have jobs, whether or not they were looking for work or on layoff in those weeks. (Because of the questionnaire design it was not possible to separate persons who reported they had been laid off from those reporting they were looking for work.)

For the purposes of this report, only persons who began spells of job search (looking for work) or layoff in 1984 and completed them in 1984 or 1985 or early 1986 are analyzed. As shown in the table below, these persons totaled 21.7 million and they experienced 26.7 million spells of job search and layoff.

Subject	Persons (thous.)	Spells (thous.)
Total.....	21,674	26,749
1 spell	17,296	17,296
2 spells	3,774	7,548
3 spells	518	1,554
4 spells	80	320
5 spells	6	30

Only a small number of spells that began in 1984 extended beyond the life of the survey (less than 2 percent). Persons with multiple spells beginning in 1984 are included (as shown above), but persons beginning spells in earlier years which ended in 1984 are excluded.

Because SIPP was designed to measure income and program participation during 2 1/2 year periods of time, the basic time unit in the survey is the month (even though the labor force data are collected in terms of weeks). This creates problems when measuring labor force activity. For example, an individual in the course of a month could begin looking for a job and then find one (unemployed and employed) or be outside the labor force and then start looking for work (not in the labor force and unemployed).

In SIPP, cases of multiple labor force statuses during a month are handled by means of a series of employment status recodes that are discussed in appendix B. Basically, what these recodes do is to classify individuals into the various combinations of statuses that are possible during a month. In this report, persons who reported that they were "looking for work or on layoff" either at some time in the month or for the entire month are considered as having a spell of job search or layoff. Moreover, looking for work or on layoff for only part of a month is counted as a full month of job search or layoff. Duration estimates of completed spells of job search and layoff, therefore, are somewhat overstated and should be considered "approximations," since not all the specific starting and ending points of spells are known from the recodes.

²See Kim B. Clark and Lawrence H. Summers, "Labor Market Dynamics and Unemployment: A Reconsideration," in *Brookings Papers on Economic Activity*, No. 1, 1979, pp. 13-72.

PERSONS BEGINNING SPELLS OF JOB SEARCH AND LAYOFF IN 1984

A total of 21.7 million persons began at least one spell of job search or layoff in 1984 that ended either in 1984, 1985, or early 1986.³ The data in table A summarize the characteristics of these persons by age, sex, race, and Hispanic origin.

The most intriguing estimates in the table concern those for women and men. According to the SIPP, 11.7 million women began spells of job search or layoff in 1984, compared with 10.0 million men. In the CPS, whether measured on a monthly or annual work experience basis, the unemployment level of women is typically smaller than it is for men. For example, according to the March supplemental questions, 9.4 million women had some unemployment in 1984, while for men, the estimate was 12.2 million. The SIPP finding suggests, of course, that more women than men may have been looking for jobs than previously believed.⁴

The difference by sex in the number of persons beginning spells of job search and layoff was particularly evident among 25- to 54-year-olds (figure 1). In this age category, women outnumbered men by 1.2 million. Women in this age group were also more numerous than men among Whites, Blacks, and Hispanics.

³According to the supplemental work experience data from the March 1985 CPS, approximately 21.5 million persons experienced some unemployment in calendar year 1984. This estimate, however, includes persons whose unemployment spells began in the previous year (or earlier) and continued into 1984.

⁴Different survey methods may account for this difference. In the monthly CPS it is possible for persons to have very short spells of unemployment between monthly interviews which are not reported to the interviewers. In the March CPS supplemental questions on work experience, short spells of unemployment occurring in the previous calendar year may be forgotten. In SIPP, however, short spells of job search or layoff may be better reported because of the 4-month reference period which is a compromise between a very short and very long reference period.

Table B presents the frequency of spells by age-sex groups, and for Whites, Blacks and Hispanics (in the course of a year an individual could have more than one spell of job search or layoff). The 21.7 million persons began, on average, 1.23 spells of job search or layoff during 1984. There was virtually no difference in the average frequency of spells for men and women. Although Blacks experienced 1.26 spells, compared with 1.23 for Whites, the difference was not statistically significant.⁵

Persons experiencing only one spell of job search or layoff constituted almost 80 percent of the total. Only 2.8 percent of the total had three or more spells that began in 1984. A slightly greater proportion of Blacks than Whites—4.5 versus 2.5 percent—began three or more spells of job search and layoff.

DURATION OF COMPLETED SPELLS OF JOB SEARCH AND LAYOFF

Estimates of the duration of completed spells of job search and layoff are also different from BLS monthly estimates of the average duration of unemployment. Theoretically, the SIPP measures the length of a spell from the time a job search or layoff began to its conclusion (whether as a result of taking a job or withdrawing from the labor force). The BLS measures the length from the time a job search or layoff began up until the time of the survey.⁶

The estimates of the duration of completed spells of job search and layoff presented in tables C and D should be considered as *approximations*. This is because

⁵As is known from the CPS, however, Blacks have a much higher "incidence" of unemployment than do Whites. For example, in 1984, 26.7 percent of Blacks 16 years and over experienced some unemployment in that year, compared with 16.2 percent of the Whites.

⁶This is sometimes referred to as an "interrupted" spell of unemployment.

B Base less than 200,000.

NOTE: Components may not add to totals because of rounding. Users of spell estimates should be aware that the associated standard errors may be underestimated. The Census Bureau is currently researching this matter.

full month of job search or layoff. Despite this tendency toward overestimation, the duration estimates provide some indication of the period of time persons spent looking for work and on layoff.

Table C presents distributions of completed spells and average completed spell lengths by age-sex groups. The average duration for the 26.7 million completed spells of job search and layoff that began in 1984 was 3.41 months. Almost one-third of the spells, or 32.7 percent, were of 1 month duration. In contrast, only 3.4 percent of them lasted 12 months or longer (figure 2).

Women experienced 14.4 million spells of job search and layoff, compared with 12.4 million for men. The

women's average duration of completed spells was less than that for men: 3.24 months versus 3.62 months. The teenage women's average was 2.97 months, but the teenage men's was 3.71 months.

The average spell duration for Blacks shown in table D was longer than for Whites and Hispanics: 3.94 months versus 3.28 and 3.34 months, respectively. (The spell durations of Whites and Hispanics were not significantly different.) Average durations for men were significantly greater than for women in the two race groups and among Hispanics. Among Black male teenagers, the spell lengths averaged 5.12 months as compared with 2.95 months for their female counterparts.

Figure 2.

The duration estimates for men and women and Blacks and Whites, even though they are approximations and conceptually different from the BLS monthly estimates, are consistent with what we know to be the relative lengths of job search and layoff for these groups.

THE CONCENTRATION OF TIME SPENT IN JOB SEARCH AND LAYOFF

Although upwards of one-third of all the spells of job search and layoff that began in 1984 were of 1 month duration, persistent unemployment is still a problem. Indeed, previous research has shown that a large part of the total time spent unemployed is accounted for by

a small proportion of persons with long periods of unemployment.⁷ The SIPP data confirm this conclusion.

Table E shows the distribution of the total months persons (who began spells in 1984) spent looking for work or on layoff by the length of the spells. One month spells, which we have shown made up 32.7 percent of all spells, contributed only 9.6 percent of the total months spent in job search and layoff. On the other hand, spells of 5 months or longer made up only 20.3 percent of all spells, but contributed 49.6 percent of all the months spent in job search and layoff.

⁷See, for example, Norman Bowers, "Probing the Issues of Unemployment Duration," *Monthly Labor Review*, July, 1980, pp. 23-32.

Among the major age-sex groups, men age 25 to 54 had the greatest concentration of months spent in persistent job search and layoff of five months or longer—56.3 percent. The comparable proportion for women was 47.2 percent. Spells of 5 months or longer accounted for 55.4 percent of all months spent in job search and layoff for Blacks, a much greater proportion than for Whites and Hispanics.

HEALTH INSURANCE AND UNEMPLOYMENT INSURANCE COVERAGE

An important dimension of an individual's spell of job search or layoff is his or her economic security during the spell. This economic security is typically dependent on the income of the household in which the person resides and his or her position in the household. If the person happens to be the chief breadwinner then the person's economic security, and that of the household, is imperiled. If, however, the person is a "first-time jobseeker" from an affluent household, the period of job search may not create any threat to their economic security.⁸

In this section we focus on whether or not persons who began spells of job search or layoff in 1984 had health insurance coverage and unemployment insurance coverage during the spell. The absence or presence of both coverages have a bearing on an individual's economic well-being during a spell of job search or layoff, even though the data presented here do not, by themselves, reflect the degree of their importance in this matter.

⁸The BLS has periodically examined the linkages between labor market problems, such as unemployment, and economic hardship. See *Linking Employment Problems to Economic Status*, U.S. Department of Labor, Bureau of Labor Statistics, Bulletin 2282, August 1987.

Health Insurance

The loss of health insurance coverage as a result of job termination has been a topical issue in public policy circles in recent years. In 1985, Federal legislation was passed requiring employers with 20 or more employees to make previously held employment-related health insurance available to workers who have been laid off (the Consolidated Omnibus Reconciliation Act of 1985, P.L. 99-272). Unemployed workers can now retain their coverage at their own expense for up to 18 months.

Table F shows the health insurance coverage status of persons during their spells of job search or layoff by their status one month before the spell. At that time, these persons may have been either employed or not in the labor force so the effect of a job loss is not fully seen.⁹ (Further analysis of this issue would involve separating and comparing these two groups.) Nevertheless, health insurance status before and during the spell for the entire group is of interest.

About 11.0 million persons (or 63.6 percent of the total with only one spell) had health insurance coverage before their spell of looking for work or layoff began. Of that total, 1.0 million had no coverage during their spell and 1.2 million had coverage only in some months. Together, this amounts to 20.1 percent of the total with either no coverage or only some health insurance coverage during their spell.

The proportion of men aged 25 to 54 who had health insurance coverage before their spells began, but then either had none or only some, was 27.4 percent. The

⁹The SIPP data analyzed here do not reflect health insurance coverage obtained through public sources, that is, through Medicare, Medicaid, CHAMPUS, and CHAMPVA. Consequently, it is possible that some portion of the persons analyzed here who reported no private health insurance coverage, may indeed have been covered by one of the public programs.

Table E. Distribution of Months of Spells of Job Search and Layoff, by Major Age-Sex Groups, Race, and Hispanic Origin

NOTE: Components may not add to totals because of rounding.

proportion for young persons 16 to 24 years old was 21.5 percent and for women 25 to 54, it was 16.9 percent. The lower proportions for young persons and women probably reflect the fact that they were more likely than men to have health insurance coverage in someone else's name. Only 8.3 percent of the persons age 55 and over had only some or no coverage during their spells.

Blacks and Hispanics who had spells of job search and layoff were more likely than Whites to have only some or no health insurance coverage after their spells began. The proportions were 29.8 percent for Blacks and 30.3 percent for Hispanics. The proportion among Whites was 19.1 percent.

The SIPP data also indicate that the likelihood of having only some or no health insurance coverage during a spell of job search or layoff rises as the length of the spell increases. Table G shows that for those persons with a 1-month spell, 7.6 percent had some or no coverage, but for those with a spell of 9 months or more, 48.0 percent had only some months or no months of health insurance coverage. Differences by these spell durations were observed for the major age-sex groups (except for those persons age 55 and over).

Unemployment Insurance

Table H contains data on the unemployment insurance coverage status of spells of job search and layoff. Unemployment insurance benefits are available to unemployed workers who have demonstrated their attachment to the labor force by a specified amount of recent work and/or earnings in covered employment. Consequently, many of the job search and layoff spells observed in the SIPP were not covered because individuals did not meet eligibility requirements.

According to the data, of the 26.7 million spells that began in 1984, approximately 16.6 percent of the total had unemployment insurance coverage in some of the months of the spells (11.7 percent had coverage in all of

the months).¹⁰ For spells of 2-month duration, coverage was observed in 15.8 percent of the spells, but in spells of 5 months or longer 36.6 percent of the spells had some coverage.¹¹

Unemployment insurance coverage of spells of 5 months or longer was more comprehensive among men age 25 to 54 (53.9 percent) and among women of the same age (45.4 percent), than among men and women age 16 to 24 (17.6 percent). This probably reflects the relative differences in these groups in meeting eligibility requirements for unemployment insurance. (The difference in coverage between men and women aged 25 to 54 was not significant.)

The coverage rate among Blacks with spells of job search and layoff was only 9.3 percent, compared with

15.6 percent for Hispanics and 18.2 percent for Whites. (The coverage rates for Hispanics and Whites were not significantly different.) Only 18.3 percent of the spells of 5 months or longer experienced by Blacks had some coverage.

OUTCOMES OF SPELLS OF JOB SEARCH AND LAYOFF

One of the advantages of SIPP longitudinal data on job search and layoff is that it is possible to find out how the spell ends. A spell may end, of course, by finding or returning to a job (a job accession) or by ceasing to look for work or losing interest in the job market (a labor force withdrawal). Table I shows the outcomes of the 26.7 million spells of job search and layoff that began in 1984 for age, sex, race, and Hispanic groups.

The findings presented here must be qualified on a number of counts. First, the economy in 1984 was recovering strongly from the 1981-82 recession and creating millions of jobs. Whether or not a similar pattern of outcomes would prevail in another phase of the

¹⁰This statistic should not be confused with unemployed persons who at a point-in-time received unemployment insurance. In many spells there may be a lag between the beginning of the spell and receipt of the benefit. In other cases, the spell may be longer than the benefit period.

¹¹Most States have a 26-week limit on the receipt of unemployment insurance benefits, although extended benefits can be received in periods of high unemployment for up to 13 additional weeks.

NOTE: Components may not add to totals because of rounding. Users of spell estimates should be aware that the associated standard errors may be underestimated. The Census Bureau is currently researching this subject.

business cycle is conjectural. Second, the full nature of the jobs persons found or returned to is not explored in this report (e.g., the occupations or industries in which the jobs were found, if they were temporary jobs), although the average hourly earnings received are examined below. And third, spells which ended due to a withdrawal from the labor force may have occurred because of either market reasons (e.g., discouragement over job prospects, wage offers too low) or nonmarket reasons (e.g., returning to school, illness). Despite these qualifications the findings are instructive and confirm earlier research.¹²

Of the spells of job search and layoff that began in 1984, 67.4 percent came to an end as the result of finding or returning to a job and 32.6 percent ended as a result of a withdrawal from the labor force. The data in Table I show that the outcome for 77.2 percent of the men's spells was a job. In contrast, 59.0 percent of the spells of women came to an end as a result of a job.

Almost 85.0 percent of the spells of men aged 25 to 54 ended in jobs, compared with 59.1 percent of the women's.

Whites were more likely to have job outcomes after their spells than Blacks and Hispanics. Slightly more than 70 percent of the spells of Whites ended with a job, compared with only 52.7 percent of the Blacks' spells and 57.8 percent of the Hispanics' spells (the difference in outcomes between Blacks and Hispanics was not significant). In other words, for whatever the reasons, Whites were more likely to complete their period of job search or layoff with a job rather than by withdrawing from the labor force.

Sharp differences in outcomes existed among young men and women by race and Hispanic origin (figure 3). Spell outcomes of White and Hispanic males age 20 to 24 were much more likely to be a job—86.7 and 84.7 percent, respectively—than was the case for Black males of the same age, 58.2 percent.¹³ In contrast, spells of White, Black, and Hispanic men aged 25 to 54

¹²One of the more well-known analyses in recent years on the outcomes of spells of unemployment is that by Clark and Summers, *op cit*.

¹³The difference in outcomes between White and Hispanic males aged 20 to 24 was not statistically significant.

Figure 3.

Outcomes of Spells of Job Search and Layoff, for Selected Groups

(Covers spells that began in 1984 and were completed by 1984, 1985, or early 1986)

were all as likely to end with jobs (around 84 to 85 percent). Last, the job search and layoff spells of White women were more likely to end with jobs than the spells of Black and Hispanic women (62.8 percent versus 44.6 and 43.2 percent).¹⁴

Job Finders' Average Hourly Earnings

The group of individuals who found or returned to jobs after a spell of job search or layoff can be disaggregated into two groups. First, there are the persons who left jobs (whether voluntarily or involuntarily) during the SIPP survey period and eventually found new jobs or returned to their old ones. For these persons we know what their hourly earnings were on the previous job as well as the hourly earnings on the job they found or returned to. The second group is composed of persons who did not report any earnings from a previous job in the survey period, but did report earnings from the job they found. These successful job finders may have been either new entrants to the labor market or re-entrants after a period of absence. As will be seen, the average hourly earnings on the jobs both groups found or returned to differed.

The table below shows the distribution of average hourly earnings for persons who reported earnings from both previous jobs and new jobs.¹⁵ Around 25 percent of the persons with new jobs had average hourly earnings of less than \$3.35 an hour, almost 50 percent had hourly earnings between \$3.35 and \$6.99, and around 25 percent had earnings of \$7.00 or more an hour. Hourly earnings on the new job averaged \$5.81 compared to \$6.18 on the previous job. This change represented a 6.0 percent reduction in the estimated wage level for these persons.

Hourly earnings	Previous job	New job
Total (in thousands)	9,514	9,514
Total (in percent)	100.0	100.0
Less than \$3.35	23.9	25.9
\$3.35 to \$4.99	26.3	26.0
\$5.00 to \$6.99	21.0	22.2
\$7.99 to \$9.99	14.8	12.8
\$10.00 or more	14.1	13.1

Table J shows the average hourly earnings on the new jobs and the previous jobs for young persons and

¹⁴The difference in outcomes between Black and Hispanic women was not statistically significant.

¹⁵Average hourly earnings were derived by dividing the person's monthly earnings by the product of his or her usual weekly hours and weeks worked in a month.

men and women 25 to 64 years old by duration of their job search or layoff. Men 25 to 64 who found or returned to jobs experienced a 10.1 percent reduction in hourly earnings—from \$8.15 to \$7.33. For women 25 to 64, hourly earnings were \$5.35 on the previous job and

\$5.10 on the new job, but the difference in the averages was not statistically significant. The average hourly earnings for young persons were virtually unchanged (figure 4).

Figure 4.

Average Hourly Earnings of Persons Who Found Jobs After Completing First Spell of Job Search and Layoff and the Average Hourly Earnings on Their Previous Job, by Major Age-Sex Group

(Covers spells that began in 1984 and were completed in 1984, 1985, or early 1986)

Average hourly earnings for persons out of work a year or more fell from \$7.41 to \$5.82. On the other hand, the drop in hourly earnings for those with spells of one month or less was from \$6.34 to \$6.11 and this change was not statistically significant. Among White workers average hourly earnings dropped from \$6.46 to \$6.01, but for Blacks earnings were largely unchanged at about \$4.65 an hour.

Table K presents the average hourly earnings for the 4.0 million persons who entered the labor force for the first time or were re-entering after an absence and found a job. The overall average for these persons was \$4.46. (Approximately 41 percent of them had average hourly earnings below \$3.35.) The majority of the individuals in this group were young persons between the ages of 16 and 24. Their average hourly earnings on the jobs they found or eventually returned to was \$4.10.

Household Incomes of Persons Not Finding Jobs

A job search or layoff which ends in a labor force withdrawal may or may not have a significant impact on a household's economic situation. This usually depends on a number of factors, such as, the household member who incurred the spell and the length of spell, alternative sources of income available to the household, the labor supply responses of other household members, and so on. In addition, household income changes may occur that are not directly linked to the spell of job

search or layoff, such as a household composition change, a windfall, or a loss. Consequently, to isolate the impact of an unsuccessful spell of job search or layoff on household income, a multiple-regression analysis would be required.

Despite the many factors that can influence household income over a period of unsuccessful job search or layoff, it is still useful to observe monthly incomes before spells begin and after they end. This is because we obtain some idea as to what happens to the economic situation of those households in which an unsuccessful job search or layoff takes place, even though causation is difficult to detect.

Approximately 7.0 million persons who began their first spell of job search or layoff in 1984 ended them by dropping out of the labor force. On average, their monthly household incomes fell from \$1,878 to \$1,737, or 7.5 percent (table L). There was little change in household income, on average, when the unsuccessful spell of job search or layoff lasted a month, but a drop of \$234 did occur when the spell lasted between 5 and 11 months.

Household incomes for men 25 to 64 who did not find or return to jobs fell by 17.4 percent, or from \$1,623 to \$1,341. Obviously, joblessness for this traditional bread-winning group has a substantial impact on household income. They constituted, however, only a small part of all unsuccessful job finders. Among young persons 16 to 24 (who made up 44.2 percent of the total), monthly household incomes declined by 7.2 percent over their

spells of job search and layoff. The change in average monthly household income for women 25 to 64 who did not find jobs was not statistically significant.

Monthly incomes in White households declined, on average, from \$2,008 to \$1,875 when a household member's spell of job search or layoff was resolved

unsuccessfully (regardless of who the household member was). In Black households, average incomes fell from \$1,420 to \$1,251 when a household member's spell outcome ended in a labor force withdrawal.¹⁶

¹⁶The difference between the decline in income for White households and the decline in income for Black households was not statistically significant.
